Course outcomes

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

BK
TP.HCM

	Course learning outcomes
L.O.1	Understanding of logic and discrete structures
	L.O.1.1 – Describe definition of propositional and predicate logic
	L.O.1.2 – Define basic discrete structures: set, mapping, graphs
L.O.2	Represent and model practical problems with discrete structures
	L.O.2.1 – Logically describe some problems arising in Computing
	L.O.2.2 – Use proving methods: direct, contrapositive, induction
	L.O.2.3 – Explain problem modeling using discrete structures
L.O.3	Understanding of basic probability and random variables
	L.O.3.1 – Define basic probability theory
	L.O.3.2 – Explain discrete random variables
L.O.4	Compute quantities of discrete structures and probabilities
	L.O.4.1 – Operate (compute/ optimize) on discrete structures
	L.O.4.2 – Compute probabilities of various events, conditional ones, Bayes theorem

Introduction

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

BK
TP.HCM

Definition

A proof is a sequence of logical deductions from
- axioms, and
- previously proved theorems
that concludes with a new theorem.

Terminology

**Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang**

BK
TP.HCM

- **Theorem** (*định lý*) = a statement that can be shown to be true
- **Axiom** (*tiên đề*) = a statement we assume to be true
- **Hypothesis** (*giả thiết*) = the premises of the theorem

Contents
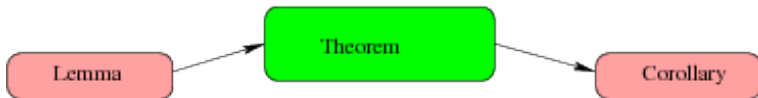

- **Lemma** (*bổ đề*) = less important theorem that is helpful in the proofs of other results
- **Corollary** (*hệ quả*) = a theorem that can be established directly from a proved theorem
- **Conjecture** (*phỏng đoán*) = statement being proposed to be true, when it is proved, it becomes theorem

Proving a Theorem

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguye
An Khuong, Le Hong
Trang

Many theorem has the form $\forall x P(x) \rightarrow Q(x)$

Goal:

- Show that $P(c) \rightarrow Q(c)$ is true with arbitrary c of the domain
- Apply universal generalization

$\Rightarrow$ How to show that conditional statement $p \rightarrow q$ is true.

Methods of Proof

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

BK
TP.HCM

- Direct proofs (*chứng minh trực tiếp*)
- Proof by contraposition (*chứng minh phản đảo*)
- Proof by contradiction (*chứng minh phản chứng*)
- Mathematical induction (*quy nạp toán học*)

Direct Proofs

Definition

A direct proof shows that $p \to q$ is true by showing that if p is true, then q must also be true.

Example

Ex.: If n is an odd integer, then n^2 is odd.

Pr.: Assume that n is odd. By the definition, $n = 2k + 1$, $k \in \mathbb{Z}$.
$n^2 = (2k + 1)^2 = 4k^2 + 4k + 1 = 2(2k^2 + 2k) + 1$ is an odd
number.

Proof by Contraposition

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

BK
TP.HCM

Definition

$p \rightarrow q$ can be proved by showing (directly) that its contrapositive, $\neg q \rightarrow \neg p$, is true.

Example

Ex.: Given an integer n, show that if $3n + 2$ is odd, then n is odd.

Pr.: Assume that "n is even", so $n = 2k$, $k \in \mathbb{Z}$. Substituting $3n + 2 = 3(2k) + 2 = 6k + 2 = 2(3k + 1)$ is even. Because the negation of the conclusion of the conditional statement implies that the hypothesis is false, *Q.E.D.*

Proofs by Contradiction

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

Definition

p is true if if can show that $\neg p \rightarrow (r \wedge \neg r)$ is true for some proposition r.

Example

Ex.: Prove that $\sqrt{2}$ is irrational.

Pr.: Let p is the proposition "$\sqrt{2}$ is irrational". Suppose $\neg p$ is true, which means $\sqrt{2}$ is rational. If so, $\exists a, b \in \mathbb{Z}$, $\sqrt{2} = a/b$, a, b have no common factors. Squared, $2 = a^2/b^2$, $2b^2 = a^2$, so a^2 is even, and a is even, too. Because of that $a = 2c, c \in \mathbb{Z}$. Thus, $2b^2 = 4c^2$, or $b^2 = 2c^2$, which means b^2 is even and so is b. That means 2 divides both a and b, contradict with the assumption.

Problem

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong

Assume that we have an infinite domino string, we want to know whether every dominoes will fall, if we only know two things:

1. We can push the first domino to fall
2. If a domino falls, the next one will be fall

We can! Mathematical induction.

Mathematical Induction

Definition (Induction)

To prove that $P(n)$ is true for all positive integers n, where $P(n)$ is a propositional function, we complete two steps:

- **Basis Step**: Verify that $P(1)$ is true.
- **Inductive Step**: Show that the conditional statement $P(k) \to P(k+1)$ is true for all positive integers k

Logic form:

$[P(1) \land \forall k P(k) \to P(k+1))] \to \forall n P(n)$

What is $P(n)$ in domino string case?

Example on Induction

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

Example

Show that if n is a positive integer, then

$$1 + 2 + \ldots + n = \frac{n(n+1)}{2}.$$

Solution

Let $P(n)$ be the proposition that sum of first n is $n(n+1)/2$

- Basis Step: $P(1)$ is true, because $1 = \frac{1(1+1)}{2}$
- Inductive Step:
  Assume that $1 + 2 + \ldots + k = \frac{k(k+1)}{2}$.
  Then:

$$
\begin{aligned}
1 + 2 + \ldots + k + (k+1) &= \frac{k(k+1)}{2} + (k+1) \\
&= \frac{k(k+1) + 2(k+1)}{2} \\
&= \frac{(k+1)(k+2)}{2}
\end{aligned}
$$

Example on Induction

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

BK
TP.HCM

Example

Prove that $n < 2^n$ for all positive integers n.

Solution

Let $P(n)$ be the proposition that $n < 2^n$.

- **Basis Step**: $P(1)$ is true, because $1 < 2^1 = 2$

- **Inductive Step**:
  Assume that $P(k)$ is true for the positive k, that is, $k < 2^k$.
  Add 1 to both side of $k < 2^k$, note that $1 \leq 2^k$.

  $$k + 1 < 2^k + 1 \leq 2^k + 2^k = 2 \cdot 2^k = 2^{k+1}.$$

  shows that $P(k + 1)$ is true, namely, that $k + 1 < 2^{k+1}$,
  based on the assumption that $P(k)$ is true.

Exercise

Prove that, if n is a non-negative integer and $7n + 9$ is an even number, then n is an odd number by three ways:

1. Directed proof.
2. Contraposition proof(phản đảo).
3. Contradiction.

Exercise

Directed proof

Assume: $7n + 9$ is the even number. Then, $7n + 9 = 2k, (k \in \mathbb{Z})$
So: $n = 2k - 6n - 9 = 2k - 6n - 10 + 1 = 2(k - 3n - 5) + 1$
That means n is an odd number.

Contrapositive proof (phản đảo)

To proof the above statement, firstly, we convert it into the logic expression: $p \to q$ with
$p = 7n + 9$ is the even number and $q = n$ is the odd number.
Its contrapositive: "If n is not an odd number, then $7n + 9$ is not an even number". We
can prove this statement follows this way:
If n is not an odd number, that means n can divisible 2. So that, $n = 2k, (k \in \mathbb{Z})$
We imply: $7n + 9 = 7(2k) + 9 = 14k + 9 = 2(7k + 4) + 1$
That means: $7n + 9$ is not the even number. Totally, we have proved the logic expression:
$\neg q \to \neg p$. Therefore $p \to q$ is also truth.

Contradiction proof

Suppose $7n + 9$ is an even number and n is not an odd number or n is an even number.
Because n is an even number, then $n = 2k, (k \in \mathbb{Z})$
We infer: $7n + 9 = 7(2k) + 9 = 14k + 9 = 2(7k + 4) + 1$
Its means: $7n + 9$ is the odd number. We can show that, if n is an even number, then
$7n + 9$ is an odd number. This contradicts with the hypothesis $7n + 9$ is an even number.

Exercise

Which of the method of proof is used for proving the statement below:

To prove *"If m and n are integers, $m \times n$ is an even number, then either m is even or n is even"*, we follow these inferences:
Assume m and n are odd numbers. Then we can express: $m = 2k + 1$ and $n = 2l + 1$. So $mn = (2k + 1)(2l + 1) = 2(2kl + k + l) + 1$ is the odd number. Contradiction. That means either m is even or n even.

- **A** Directed proof.
- **B** Contradiction proof or contra-positive proof
- **C** inductive proof
- **D** All the above answers are incorrect.

Exercise

What is wrong in the following induction to prove that all flowers are the same color?

1. Let $P(n)$ be all flowers in a set of n flowers have the same color.

2. We can easily infer that, $P(1)$ is a truth.

3. Assume that $P(n)$ is correct. Which means that all flowers in the set of n flowers have the same color .

4. Consider a set of $n + 1$ flowers; numbering as $1, 2, 3, \ldots, n, (n + 1)$.

5. Based on the assumption, Sequence of first n flowers has the same color, and sequence of n later flowers also has the same color.

6. Because the 2 set has same $n - 1$ flowers, all $n + 1$ flowers should have a same color.

7. Meaning $P(n + 1)$ and the statement is proved by induction.

Consider a subset D ($\mathcal{N} \times N$) which defined in a recursive way:

  ⓘ $(n, 0) \in D$.

  ⓘ If $(n, m) \in D$, $(n, n + m) \in D$.

Do

  ❶ Calculate some elements from D.

  ❷ prove by induction on k that 'if $m = k.n$, '$(n, m) \in D$'.

  ❸ prove that if $(n, m) \in D$, we will get $m = kn$ $k \in \mathcal{N}$.

a) Prove that $\forall n \in \mathcal{N}^+$
$(n+1)^2 - (n+2)^2 - (n+3)^2 + (n+4)^2 = 4$.

b) The infer that for every natural number m, there exists natural number n that can represent m as a sum of squares 1^2, 2^2, ..., n^2, which mean: $\forall m \in \mathcal{N}^+$, $\exists n \in \mathcal{N}^+$, $\exists \varepsilon_1, \ldots, \varepsilon_n \in \{-1, 1\}$, $m = \varepsilon_1 1^2 + \varepsilon_2 2^2 + \ldots + \varepsilon_n n^2$.

Prove the following:

1. $1.2 + 2.5 + 3.8 + \ldots + n.(3n - 1) = n^2(n + 1), n \geq 1$
2. $1 + \frac{1}{1+2} + \frac{1}{1+2+3} + \ldots + \frac{1}{1+2+3+\ldots+n} = \frac{2n}{n+1}, n \geq 1$
3. $\sum_{i=1}^{n} 2^{i-1} = 2^n - 1$
4. $\log_5 (2)$ is an irrational number.

**Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang**

Solution

BK
TP.HCM

(1) $1.2 + 2.5 + 3.8 + \ldots + n.(3n-1) = n^2(n+1), n \geq 1$ (1)
- With $n = 1$ we have $1.2 = 1^2(1+1) \rightarrow$ (1) correct.
- Assume (1) is correct with $n = k$, then we have
$1.2 + 2.5 + 3.8 + \ldots + k.(3k-1) = k^2(k+1)$
- We will prove (1) is correct with $n = k+1$, meaning
$1.2+2.5+3.8+\ldots+k.(3k-1)+(k+1)(3k+2) = (k+1)^2(k+2)$.
In fact, $n = k+1$, meaning
$1.2 + 2.5 + 3.8 + \ldots + k.(3k-1) + (k+1)(3k+2) =$
$[1.2 + 2.5 + 3.8 + \ldots + k.(3k-1)] + (k+1)(3k+2) =$
$k^2(k+1) + (k+1)(3k+2) = (k+1)(k^2 + 3k + 2) =$
$(k+1)(k+1)(k+2) = (k+1)^2(k+2)$.
The expression is correct with $n = k+1$.Thus, QED.

Solution

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

BK
TP.HCM

(2) $1 + \frac{1}{1+2} + \frac{1}{1+2+3} + \ldots + \frac{1}{1+2+3+\ldots+n} = \frac{2n}{n+1}, n \geq 1$ (2)

- With $n = 1$ we have P(1): $1 = \frac{2}{1+1} \rightarrow$ (2) correct.
- Assume (2) is correct with $n = k$, Then we have P(k):
$1 + \frac{1}{1+2} + \frac{1}{1+2+3} + \ldots + \frac{1}{1+2+3+\ldots+k} = \frac{2k}{k+1}$
- We will prove (2) is correct with $n = k + 1$, meaning
P(k+1):
$1 + \frac{1}{1+2} + \frac{1}{1+2+3} + \ldots + \frac{1}{1+2+3+\ldots+k} + \frac{1}{1+2+\ldots+k+(k+1)} =$
$\frac{2k}{k+1} + \frac{1}{1+2+\ldots+k+(k+1)} = \frac{2k}{k+1} + \frac{2}{(k+1)(k+2)} = \frac{2k(k+2)+2}{(k+1)(k+2)} =$
$\frac{2(k^2+2k+1)}{(k+1)(k+2)} = \frac{2(k+1)^2}{(k+1)(k+2)} = \frac{2(k+1)}{k+2}$ [Noted that:
$1 + 2 + \ldots + k + (k+1) = \frac{(k+1)(k+2)}{2}$]
The expression is correct with $n = k + 1$. Thus, QED.

Solution

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguye
An Khuong, Le Hong
Trang

BK
TP.HCM

(3) $\sum_{i=1}^{n} 2^{i-1} = 2^n - 1$ (3)
- With $i = 1$ we have S(1): $\sum_{i=1}^{1} 2^{i-1} = 2^{1-1} = 2^1 - 1 \rightarrow$ (3) correct.
- Assume (3) is correct with $n = k$, Then we have S(k): $\sum_{i=1}^{k} 2^{i-1} = 2^k - 1$
- We will prove (3) is correct with $n = k + 1$, meaning S(k+1):
$\sum_{i=1}^{k+1} 2^{i-1} = \sum_{i=1}^{k} 2^{i-1} + 2^k = 2^k - 1 + 2^k = 2^{k+1} - 1$
The expression is correct with $n = k + 1$.

(4) Prove that $\log_5(2)$ is an irrational number.
Assume the opposite $\log_5(2)$ is a rational number. Therefore, $\log_5(2) = \frac{a}{b}$, where $a, b \in \mathbb{Z}$, $b \neq 0$, GCD(a,b) = 1
Then, $5^{\frac{a}{b}} = \sqrt[b]{5^a} = 2 \Leftrightarrow 5^a = 2^b$. Because 5^a is always odd and 2^b is always even. So, this is a contradiction. Thus, QED.

Exercise

Prove the following statements by induction:

1. For every integer $n \geq 1$, $3^{2n-1} + 1$ is divisible by 4.
2. For every integer $n \geq 1$, $6^n - 1$ is divisible by 5.
3. For every integer $n \geq 1$, $5^{2n-1} + 1$ is divisible by 6.
4. For every integer $n \geq 1$, $8^n - 1$ is divisible by 7.
5. For every integer $n \geq 1$, $4^n + 15n - 1$ is divisible by 9.

Solution

(1) Prove that for every integer $n \geq 1$, $3^{2n-1} + 1$ is divisible by 4.

With $n = 1$, we have $4 \vdots 4$ - Truth.
On the other hand, There is an integer $k \geq 1$ so that
$3^{2k-1} + 1$ is divisible by 4.
On the other hand, There is an integer m so that
$3^{2k-1} + 1 = 4m$.
We need to prove $3^{2(k+1)-1} + 1$ is divisible by 4.
This is the equivalent to prove $3^{2k+1} + 1$ is divisible by 4.
On the other hand, we have:
$3^{2k+1} + 1 = 3^2(3^{2k-1} + 9 - 8 = 9(3^{2k-1} + 1) - 2.4 = 4(9m + 2)$.
Therefore, $3^{2k+1} + 1$ is a multiple of 4. The above statement
is proved by induction

Solution

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

BK
TP.HCM

(2) Prove that for every integer $n \geq 1$, $6^n - 1$ is divisible by 5.

With $n = 1$, we have $6^1 - 1 = 5 \vdots 5$ - Truth.
On the other hand, There is an integer $n \geq 1$ so that $6^n - 1$ is divisible by 5.
On the other hand, There is an integer m so that $6^n - 1 = 5m$.
We need to prove $6^{n+1} - 1$ is divisible by 5.
On the other hand, we have:
$6^{n+1} - 1 = 6.6^n - 6 + 5 = 6(6^n - 1) + 5 = 30m + 5 = 5(6m + 1)$.
Therefore, $6^{n+1} - 1$ is a multiple of 5. The above statement is proved by induction.

Solution

BK
TP.HCM

(3) Prove that for every integer $n \geq 1$, $5^{2n-1} + 1$ is divisible by 6.

With $n = 1$, we have $5^{2-1} + 1 = 4 \vdots 4$ - Truth.
Assume there is an integer $n \geq 1$ so that $5^{2n-1} + 1$ is divisible by 6.
On the other hand, There is an integer m so that $5^{2n-1} + 1 = 6m$.
We have to prove $5^{2(n+1)-1} + 1$ is divisible by 6.
This is the equivalent to prove $5^{2n+1} + 1$ is divisible by 6.
On the other hand, we have:
$5^{2n+1} - 1 = 5^2 . 5^{2n-1} + 25 - 24 = 5^2(5^{2n-1} + 1) - 24 = 150m - 24 = 6(25m - 4)$. Therefore, $5^{2n-1} + 1$ is a multiple of 6. The above statement is proved by induction.

Solution

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

(4) Prove that for every integer $n \geq 1$, $8^n - 1$ is divisible by 7.

With $n = 1$, we have $8^1 - 1 = 7 \vdots 7$ - Truth.
Assume there is an integer $n \geq 1$ so that $8^n - 1$ is divisible by 7.
In other word, there exists an integer m so that $8^n - 1 = 7m$.
We need to prove that $8^{n+1} - 1$ is also divisible by 7.
On the other hand, We have:
$8^{n+1} - 1 = 8.8^n - 8 + 7 = 8(8^n - 1) + 7 = 56m + 7 = 7(8m + 1)$.
Thus, $8^{n+1} - 1$ is also a multiple of 7. The above statement is proved by induction.

Tran Tuan Anh, Nguyen
An Khuong, Le Hong
Trang

BK
TP.HCM

Solution

(5) Prove that for all integers $n \geq 1$, $4^n + 15n - 1$ are divisible by 9.

With $n = 1$, we has $4^1 + 15 - 1 = 18 \vdots 9$ - Always true.

Assume there is an integer $n \geq 1$ so that $4^n + 15n - 1$ is divisible by 9

In other word, There is an integer m so that

$4^n + 15n - 1 = 9m$

We need to prove that $4^{n+1} + 15(n+1) - 1$ is also divisible by 9.

Solution

On the other hand, we have:

$4^{n+1} + 15(n+1) - 1 = 4^n.4^1 + 15n + 15 - 1 =$
$3.4^n + 4^n + 15n + 15 - 1 = (4^n + 15n - 1) + 3.4^n + 15$

In which: $(4^n + 15n - 1) \vdots 9$ (based on the assumption)

And: For $3.4^n + 15 = 3(4^n + 5)$ divisible by 9, we need to prove

$(4^n + 5) \vdots 3$

Let $B(k) = 4^k + 5$. With $k = 1$, $4^1 + 5 = 9 \vdots 3 \to$ correct with $k = 1$

Assume it is also true with $k = i \to B(i) = (4^1 + 5) \vdots 3$. We prove
that it is also correct with $k = i + 1 \to B(i+1) =$
$4^{i+1} + 5 = 4^i.4 + 5 = 3.4^i + 4^i + 5 = (4^i + 5) + 3.4^i$. We have:

$(4^i + 5) \vdots 3$ based on the assumption

And: $3.4^i \vdots 3$. Therefore, $(4^n + 5) \vdots 3$. thus, QED.

3.32

Prove the following inequalities by induction:

1. For every integer $n \geq 1$, $3^n > n^2$.

2. For every integer $n \geq 4$, $n! > 2^n$.

Solution

Huynh Tuong Nguyen,
Tran Tuan Anh, Nguye
An Khuong, Le Hong
Trang

BK
TP.HCM

(1) Prove that for every integer $n \geq 1$, $3^n > n^2$.
with $n = 1$, we have $3^1 = 3$ và $1^2 = 1$. Therefore, the
statement is correct for $n = 1$.
With $n = 2$, we have $3^2 = 9$ and $2^2 = 4$. Therefore, the
statement is also correct with $n = 2$.
Assume there is an integer $n \geq 2$ that $3^n > n^2$.
We need to prove 3^{n+1} is greater than $(n+1)^2$.
On the other hand, Expanding the right side of the inequality,
we get: $(n+1)^2 = n^2 + 2n + 1$.
Because we only consider $n \geq 2$, $n^2 = n \times n \geq 2n$ and
$3^n > 1$.
Consider the left side of the inequality:
$3^{n+1} = 3 \times 3^n = 3^n + 3^n + 3^n > n^2 + n^2 + 1 >$
$n^2 + 2n + 1 = (n+1)^2$ (QED)
. Thus, The statement is proved by induction.

3.34

Trang

Solution

(2) Prove that for every integer $n \geq 4$, $n! > 2^n$.
   with $n = 4$, we have $4! = 24 > 2^4 = 16$.
   Assume there is an integer $n \geq 1$ that $n! > 2^n$.
   We need to prove that $(n+1)!$ is greater than 2^{n+1}.
   On the other hand, we have:
   $(n+1)! = (n+1) \times n!$. based on the assumption, we have:
   $(n+1)! > (n+1) \times 2^n$.
   Moreover, the expression on the right side is greater than
   $2 \times 2^n = 2^{n+1}$ (vì $n \geq 4 > 2$) because of that, the above
   statement is proved by induction.
